

# DOWNLIGHTS

## Which Beam Angle?

A 25 Degree beam angle is more focused and intense. This more narrow beam should be used to illuminate specific objects. A good example of using this would be inside a shower cubicle.

A 40 Degree beam angle spreads the light out more effectively. This flood style beam should be used to illuminate an area rather than a specific object. A good example of using this would in a room that had multiple downlights which provided the main source of light.
